

FTTH uses OTDR to test the module s $\pm 0.05\text{dB}$ accuracy

Overview

OTDR testing plays a crucial role in ensuring the performance and reliability of Passive Optical Networks (PON) and Fibre to the Home (FTTH) installations. By using an Optical Time Domain Reflectometer (OTDR), network technicians can detect faults, measure attenuation, and assess. Statistics from multiple ISP field reports show that over 70% of FTTH faults originate in passive infrastructure, including: Active equipment such as OLTs or ONTs fail far less frequently. This means FTTH maintenance teams must focus primarily on: And this is exactly where OTDR testing becomes. OTDR settings are a balance between dynamic range, acquisition time, spatial resolution and accuracy. An OLTS provides the most accurate insertion loss measurement on a link by using a light source on one end and a power meter at the other to measure precisely how much light is coming out at the opposite end.
