The transformer substation needs to be double grounded

Overview

When there are two or more graded insulation transformers running in parallel in the substation, only one part of the transformer neutral point is considered to be grounded, while the other part of the transformer neutral point is grounded through the gap to. This is important to understand, because transformers will, in most cases, require a bonded connection to ground to be considered properly grounded per NEC Article 250. As we wrap up this series, this article outlines the purpose of substation grounding, the IEE Std 80 design, and best-practice field testing. A properly engineered ground grid limits hazardous voltage gradients during faults, provides. Transformer neutral grounding refers to the intentional connection of a transformer's neutral point—typically on the secondary winding—to ground.
